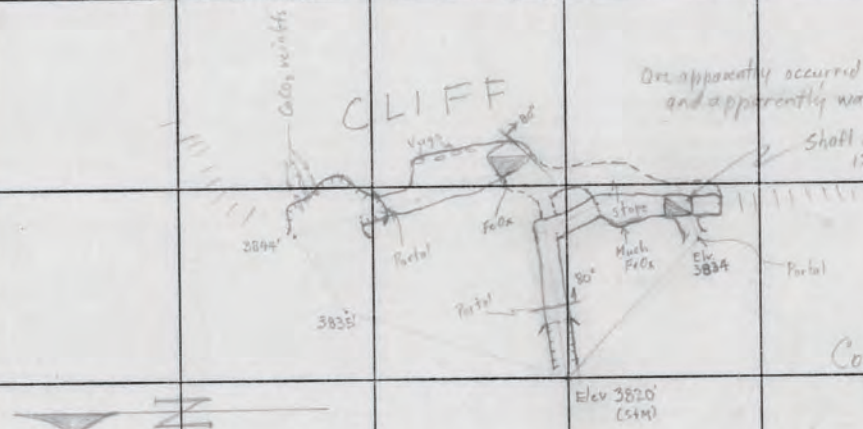
BANTA + INMAN — NEW LEADVILLE — Upper Workings — SEPT 22, 1955



Ore apparently occurred as scattered bunches + pods and apparently was not extensive. No ore mineralization was to be seen in place. Rock for most part is undisturbed; little or no breccia and almost no faulting apparent. Ore must have occurred in stope where it lay parallel to strike of fractures (N10°W & 50°W). Fractures may be essentially bedding features though some are surely not.

Country rock is dark gray and black, dense limestone (massive)
